Impact of AI probably depends a lot on how we use it

Is there a limit to complexity of concepts that we as individuals can be trained to understand?
Is there a limit to the size of effective teams (Amdahl's law for human teaming) ?

Where do I stand?

Where do I stand?

Co-founded an AI start-up P-1.ai.

We are building an engineering AGI. We closed a \$23 million seed round led by Radical Ventures.

Where do I stand?

SRI Spinoff focused on manufacturing and supply networks ..

The artificial general manufacturing intelligence agent

The most impact from AI will be in amplifying human ingenuity and enabling much larger collaboration than currently feasible.

Three Major Dimensions of the Challenge of Robust Learning

No machine learning paradigm can match the plasticity, efficiency, and reasoning capability of the human brain.

Predictive Processing – a Theory of Mind

Predictive coding (also known as predictive processing) is **a theory of mind in which the mind is constantly generating and updating a mental model of the environment**. The model is used to generate predictions of sensory input that are compared to actual sensory input.

Rao and Ballard'99, Friston and Kiebel'09 Stefanics et. al.'14

Human perception is model-based, using our context to bias the interpretation of sensors.

Predictive Processing – a Theory of Mind

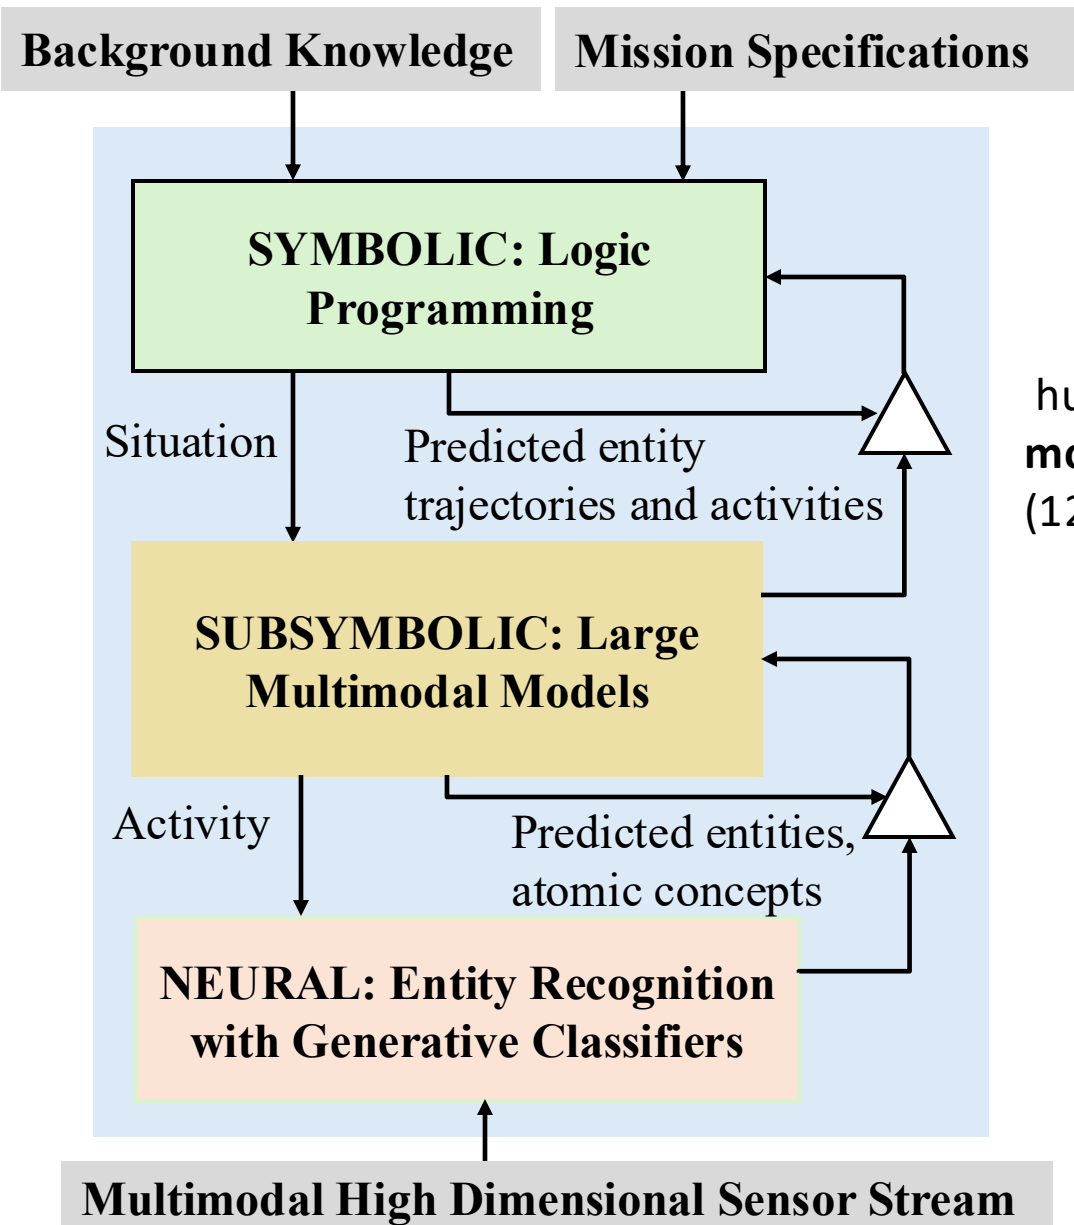

Human perception is model-based, using our context to bias the interpretation of sensors.

Predictive Processing – a Theory of Mind

Human perception is model-based, using our context to bias the interpretation of sensors.

TrinityAI: Neuro-symbolic Architecture Inspired by Predictive Coding

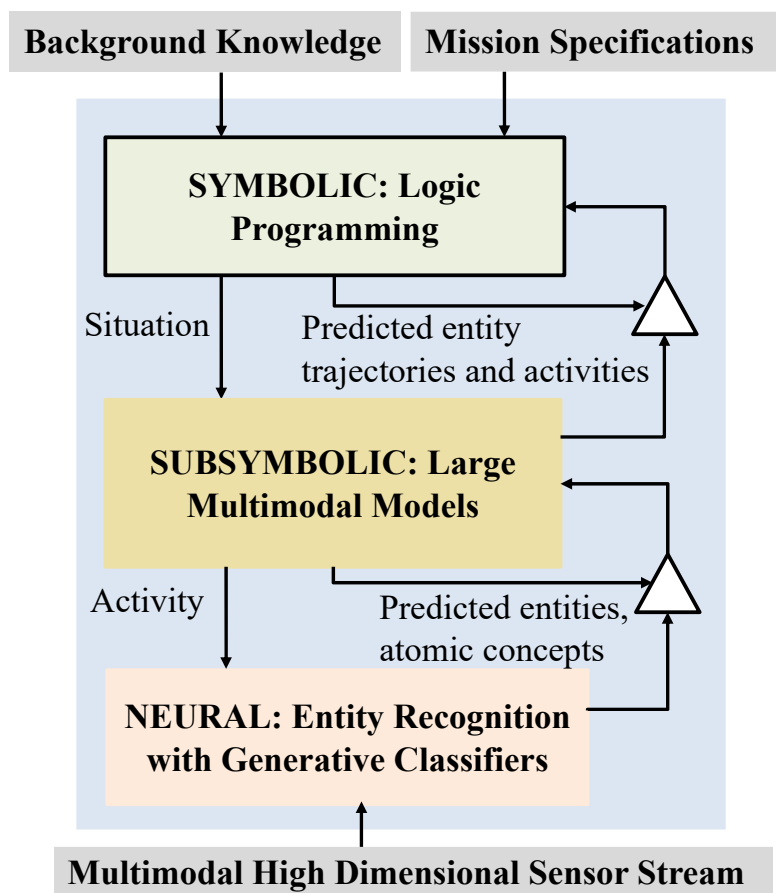

human (19.46%), **bicycle (1.04%)**, **motorcycle (1.11%)**, car (43.62%), truck (12.70%), movable_object (22.05%)

Comparison with other neuro-symbolic architectures

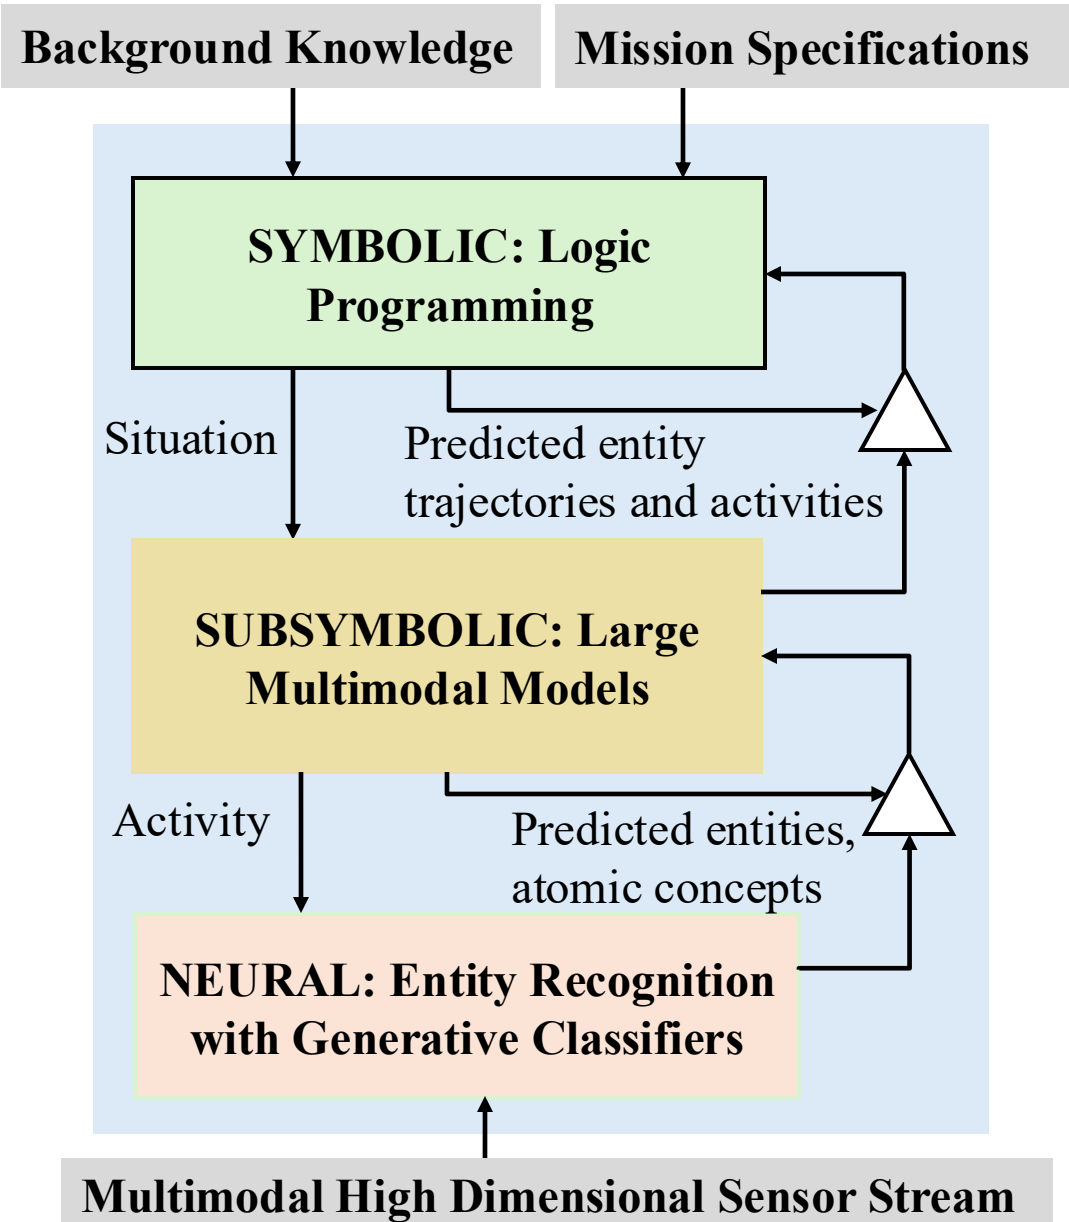

Predicting using more abstract concepts

Predicting using *larger* contexts

Self-stabilizing loops across layers make TrinityAI robust to adversarial perturbations.

Uncertainty Quantification Key to Robust Neuro-symbolic Architecture

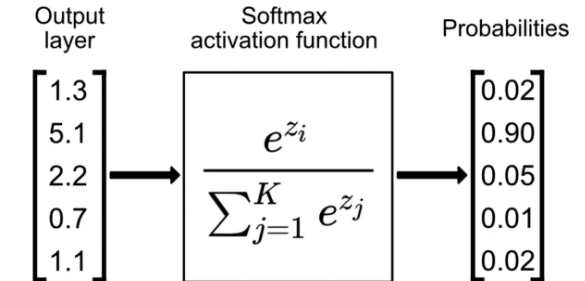

Each layer should produce **not a decision but a distribution** over decisions.

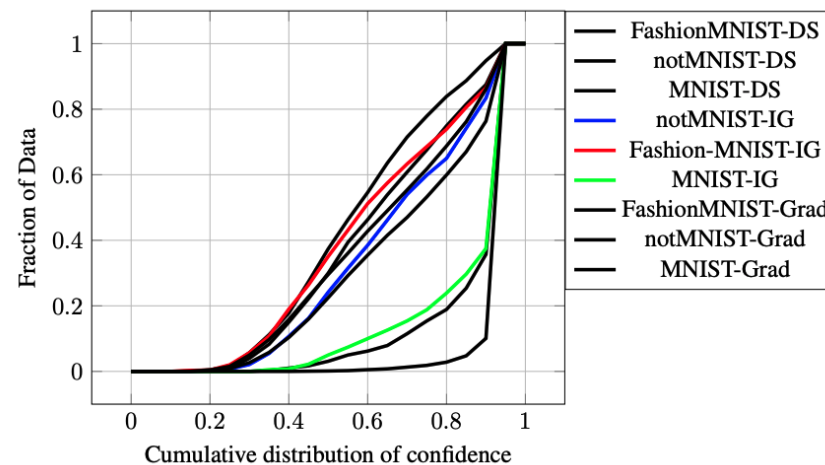

Disagreement between layers can be measured using **distance over distributions** (e.g. Wasserstein, KL)

Lack of Calibration in Deep Learning Models

ML models generalize to inputs from the training distribution.
For inputs **out of this distribution (OODs)**, models can produce incorrect outputs with high confidence (softmax value).

Guo, Chuan, et al. "On calibration of modern neural networks." *ICML*, 2017.

Jha, Susmit, et al. "Attribution-based confidence metric for deep neural networks." *Neurips*, 2019

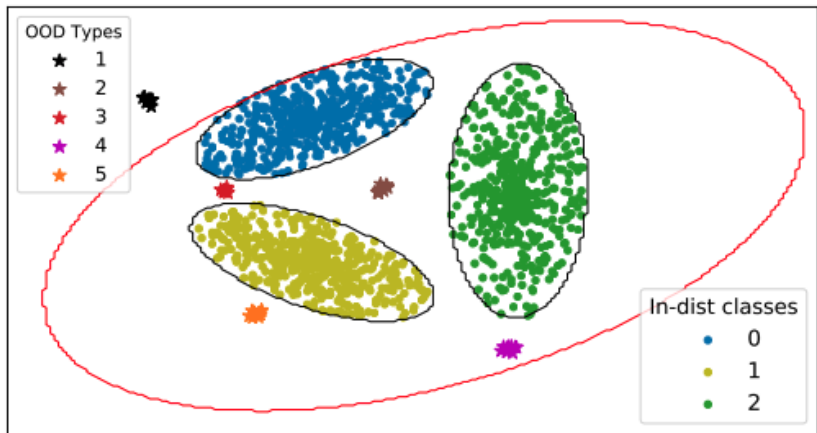

Spieß et al. "Calibration and correctness of language models for code." *ICSE* 2025

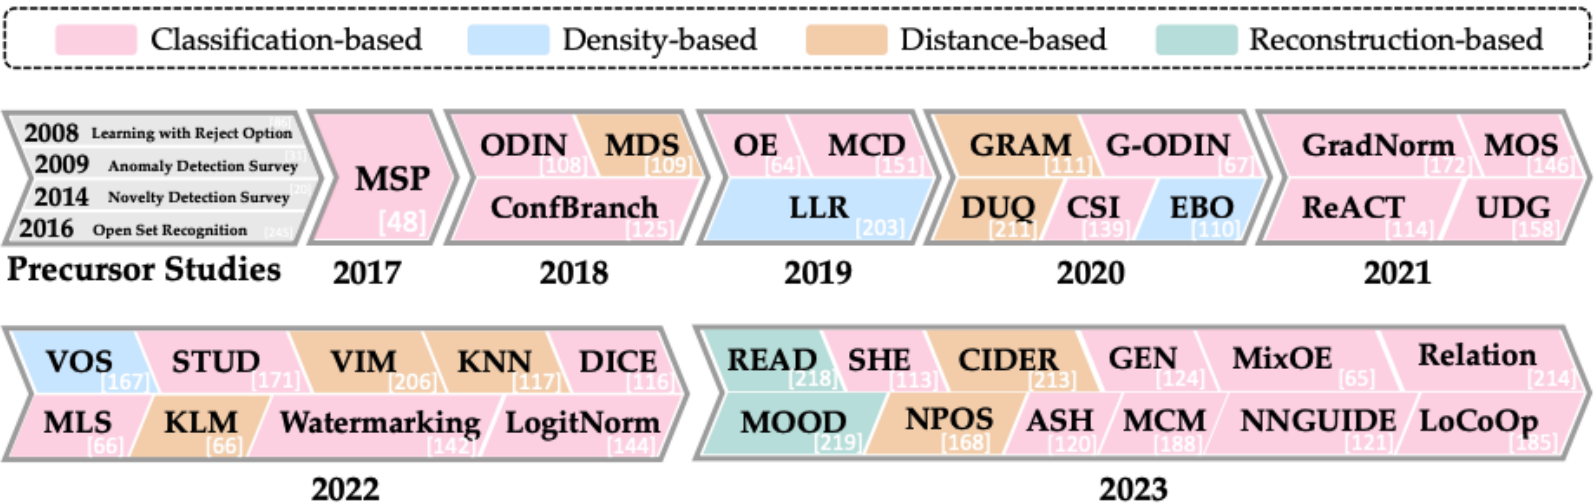

Both discriminative and generative models (small and large) lack calibration.

OOD inputs can have different aleatoric or epistemic uncertainty

Detect whether an input is OOD and the model's output cannot be trusted on it.

Jha et. al. "On detection of out of distribution inputs in deep neural networks." *CogMI*. IEEE, 2021.

Yang, J., Zhou, K., Li, Y., & Liu, Z.. Generalized out-of-distribution detection: A survey. *International Journal of Computer Vision*, 2024

Plethora of different scores used to detect OODs that work for different classes of OODs

Combining diverse scores with false alarm guarantees

- Given multiple different OOD scoring functions $s^i(\cdot)$, we can compute scores (lower for in-distr data) for any input X as $T^i(X) = s^i(X)$
- Any arbitrary combination of these scores can be insufficient.

For instance, consider the scenario where $(T^1, T^2) \sim \mathcal{N}((1, -1), I)$, a combination

$$T = T^1 + T^2$$

has the same distribution under null and alternative hypothesis making it ineffective.

Magesh et. al. "Principled out-of-distribution detection via multiple testing." *Journal of Machine Learning Research* 24, no. 378 (2024): 1-35.

The null hypothesis is that the input is in distribution; input is OOD if null hypothesis is rejected.

Combining diverse scores with false alarm guarantees

- Given multiple different OOD scoring functions $s^i(\cdot)$, we can compute scores (lower for in-distr data) for any input X as $T^i(X) = s^i(X)$
- Split into K hypothesis testing problems and combine the outcomes:

$$\begin{array}{ll} H_{0,1} : T_{\text{test}}^1 \sim P^1 & H_{1,1} : T_{\text{test}}^1 \not\sim P^1 \\ \vdots & \\ H_{0,K} : T_{\text{test}}^K \sim P^K & H_{1,K} : T_{\text{test}}^K \not\sim P^K \end{array}$$

- The null hypothesis is that the input is in distribution. $\forall i \in [1, K] \ H_0 \Rightarrow H_{0,i}$
- Since in-training distribution is unknown, we replace p-values with **conformal p-values**.

Magesh et. al. "Principled out-of-distribution detection via multiple testing." *Journal of Machine Learning Research* 24, no. 378 (2024): 1-35.

We declare an input to be OOD if any of the hypothesis test rejects the null hypothesis.

Combining diverse scores with false alarm guarantees

Algorithm 1 BH based OOD detection test with conformal p-values

Inputs:

New input X_{test} ;

Scores over \mathcal{T}_{cal} as $\left\{ \{T_j^1 = s^1(X_j) : j \in \mathcal{T}_{\text{cal}}\}, \dots, \{T_j^K = s^K(X_j) : j \in \mathcal{T}_{\text{cal}}\} \right\}$;

ML model $f(\mathbf{W}, \cdot)$;

Desired conditional probability of false alarm $\alpha \in (0, 1)$.

Algorithm:

For X_{test} , compute scores T_{test}^i .

Calculate conformal p-values as:

$$\hat{Q}^i = \frac{1 + |\{j \in \mathcal{T}_{\text{cal}} : T_j^i \geq T_{\text{test}}^i\}|}{1 + |\mathcal{T}_{\text{cal}}|}.$$

Order them as $\hat{Q}^{(1)} \leq \hat{Q}^{(2)} \leq \dots \leq \hat{Q}^{(K)}$.

Calculate $m = \max \left\{ i : \hat{Q}^{(i)} \leq \frac{\alpha i}{C(K)K} \right\}$. $C(K) = (1 + \epsilon) \sum_{j=1}^K \frac{1}{j}$.

Output:

Declare OOD if $m \geq 1$.

Lemma 1 Let $\epsilon > 0$, K and α be as in Algorithm 1. Let $a_j = \lfloor (n_{\text{cal}} + 1) \frac{\alpha j}{C(K)K} \rfloor$, $b_j = (n_{\text{cal}} + 1) - a_j$, and $\mu_j = \frac{a_j}{a_j + b_j}$. For a given $\delta > 0$, let n_{cal} be such that

$$\min_{j=1,2,\dots,K} I_{(1+\epsilon)\mu_j}(a_j, b_j) \geq 1 - \frac{\delta}{K^2},$$

where $I_x(a, b)$ is the regularized incomplete beta function (the CDF of a Beta distribution with parameters a, b). Then for random variables $r_j^i \sim \text{Beta}(a_j, b_j)$ for $j = 1, \dots, K$,

$$P \left\{ \bigcap_{i=1}^K \bigcap_{j=1}^K \left\{ r_j^i \leq (1 + \epsilon) \frac{\alpha j}{C(K)K} \right\} \right\} \geq 1 - \delta.$$

(a) $\alpha = 0.1$

(b) $\alpha = 0.05$

$\epsilon = 1, K = 5$

Magesh et. al. "Principled out-of-distribution detection via multiple testing." *Journal of Machine Learning Research* 24, no. 378 (2024): 1-35.

The size of the calibration set depends on the false alarm rate and the number of scores.

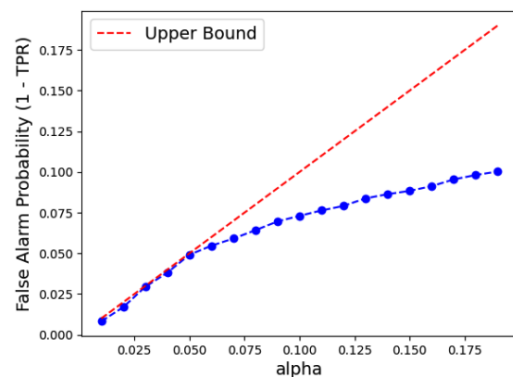

Combining diverse scores with false alarm guarantees

(a) ResNet with CIFAR10

(b) DenseNet with CIFAR10

(c) ResNet with SVHN

(d) DenseNet with SVHN

Theorem 2 Let $\alpha, \delta \in (0, 1)$. Let \mathcal{T}_{cal} be a calibration set, and let n_{cal} be large enough (as defined in the Lemma 1). Then, for a new input X_{test} and an ML model $f(\mathbf{W}, \cdot)$, the probability of incorrectly detecting X_{test} as OOD conditioned on \mathcal{T}_{cal} while using Algorithm 1 is bounded by α , i.e.,

$$P_F(\mathcal{T}_{\text{cal}}) = P_{H_0}(\text{declare OOD} | \mathcal{T}_{\text{cal}}) \leq \alpha,$$

with probability $1 - \delta$.

Magesh et. al. "Principled out-of-distribution detection via multiple testing." *Journal of Machine Learning Research* 24, no. 378 (2024): 1-35.

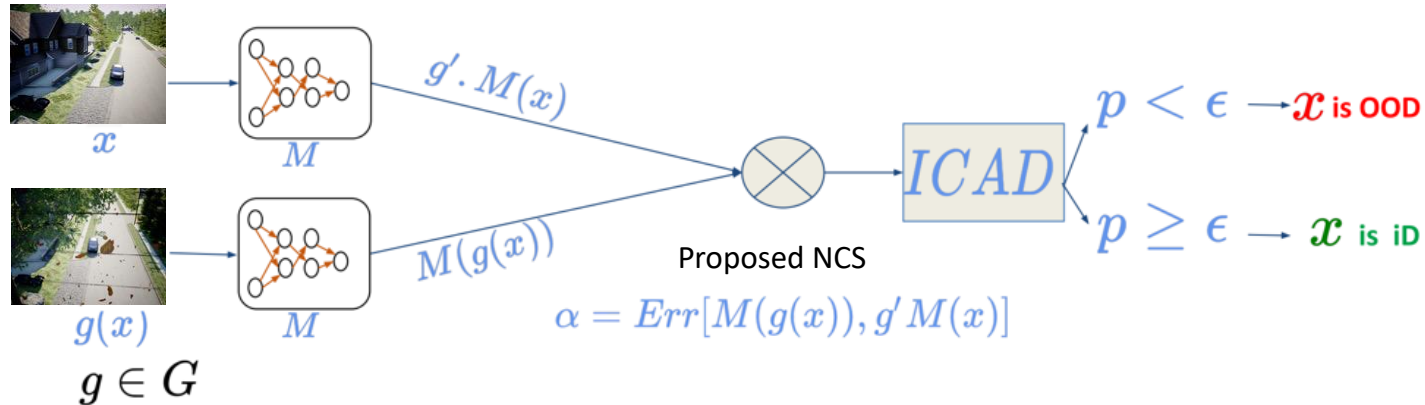

We can combine different scores and provide a false alarm guarantee that is empirically tighter when required false alarm rate is low.

Combining diverse scores with false alarm guarantees

OOD Dataset	Method	ResNet34	DenseNet
SVHN	Mahala (penultimate layer)	82.77	92.98
	Gram (sum across layers)	96.04	89.97
	Energy	73.21	42.40

	Ours - Mahala, Energy ($5/4 + 1$)	91.88	94.03
	Ours - Gram, Energy ($5/4 + 1$)	96.78	90.77
	Ours - Mahala, Gram ($5/4 + 5$)	96.23	94.21
	Ours - Mahala, Gram and Energy ($5/4+5/4+1$)	97.13	94.57
ImageNet	Mahala (penultimate layer)	85.45	82.81
	Gram (sum across layers)	92.34	80.04
	Energy	76.76	94.93
	Naive Averaging ($5/4 + 5/4 + 1$)	86.45	80.96
	Bonferroni - Mahala, Gram and Energy ($5/4+5/4+1$)	95.92	95.89
	Ours - Mahala ($5/4$)	96.90	95.19
	Ours - Gram ($5/4$)	92.60	80.12
	Ours - Mahala, Energy ($5/4 + 1$)	97.28	98.09
	Ours - Gram, Energy ($5/4 + 1$)	94.53	95.19
	Ours - Mahala, Gram ($5/4 + 5$)	96.38	92.81
	Ours - Mahala, Gram and Energy ($5/4+5/4+1$)	97.03	97.20

Across different pairs of in-distribution and out-of-distribution datasets and across different architectures, our combination of different scores shows a better detection rate in addition to false alarm guarantee.

Invariance/Equivariance and Extension to Time-Series Data

Transform input that is **invariant or equivariant** and use the difference between the inference between the original and transformed input to compute OOD scores.

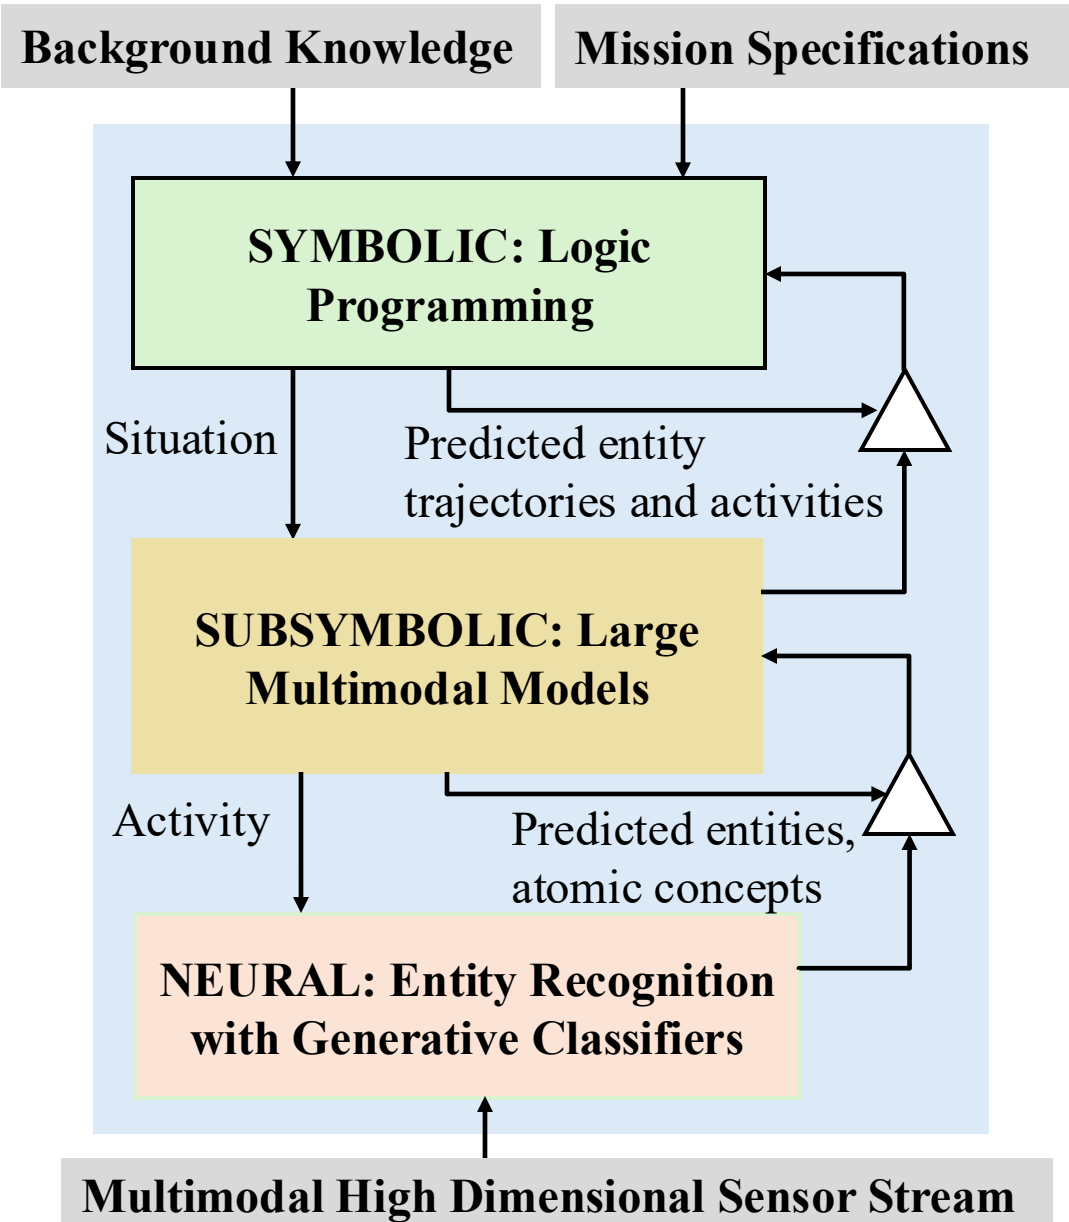

Kaur, R. et. al. "iDECODe: In-Distribution Equivariance for Conformal Out-of-Distribution Detection". AAAI, 2022.
Lin et. al. Safety Monitoring for Learning-Enabled CPS in Out-of-Distribution Scenarios. ICCPS, 2025.

Extensions to **time series** such as **videos**: Consider temporal transformations such as frame-drop, local reordering, etc.

Kaur, R. et. al. "CODiT: Conformal out-of-distribution Detection in time-series data for cyber-physical systems". ICCPS, 2023.

Uncertainty Quantification Key to Robust Neuro-symbolic Architecture

Each layer should produce **not a decision but a distribution** over decisions.

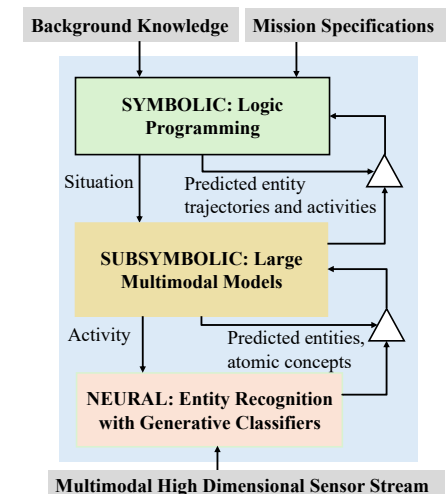

Disagreement between layers can be measured using **distance over distributions** (e.g. Wasserstein, KL)

Compositional Novelty and Out of Context detection

Objects violating common contextual relations, such as co-occurrence, size, and shape relations, in a scene, resulting in compositional novelty.

Acharya et. al. "Detecting out-of-context objects using graph context reasoning network." In *IJCAI* 2022.

Roy et. al. "Zero-shot Detection of Out-of-Context Objects Using Foundation Models" WACV 2025.

Compositional Novelty and Out of Context detection

Dataset	VLM	GNN (IJCAI'22)	Ours (WACV'25)
MIT-OOC	23.45	73.29	90.82
IJCAI22-OOC	26.78	84.85	87.26

Acharya et. al. "[Detecting out-of-context objects using graph context reasoning network.](#)" In *IJCAI* 2022.

Roy et. al. "[Zero-shot Detection of Out-of-Context Objects Using Foundation Models](#)" WACV 2025.

Neuro-symbolic approach performs better than our prior work with custom-trained GNN without any training and significantly outperforms VLMs.

Failure Cases Needing Quantitative Reasoning

087: a silver car that is parked in front of a brick building

219: a man standing on a street corner talking on a cell phone

063: a refrigerator filled with food and drinks with a white door

134: a truck and a taxi are driving down a street

104: a large sign on a gravel road in the middle of a field

068: a bathroom with a toilet and a wall with a lot of rolls of toilet paper

189: a man riding a small motorcycle down a street in front of a house

Lack of quantitative reasoning is a key limitation of our current neuro-symbolic approach.

Vehicle Design for Rugged Terrain Using Reinforcement Learning

- RL exploration stops using square or cylindrical wheels and starts mostly using **sphere wheels**.
- Further, it prefers using **large cylinder** as the base chassis design and adds a **number of chassis segments** to improve the vehicle's ability to climb over obstacles.

About EELS (Exobiology Extant Life Surveyor)

EELS is designed to go places no one has ever seen before, on its own, without real-time human input. The concept for this self-propelled, autonomous robot was inspired by the desire to descend the narrow, geyser-spewing vents in the icy crust of Saturn's moon Enceladus in order to look for signs of life in the ocean below.

FACTOID

3D Situational Awareness

The EELS head "sees" and interprets the world using lidar and four stereo camera pairs, creating a 3D map of its environment.

FACTOID

Active Skin Locomotion

Independently actuated counter-rotating screws provide propulsion, traction, and grip on icy terrain and in unconsolidated material like snow and sand.

FACTOID

Many Degrees of Freedom

EELS is able to adopt multiple shape configurations to adapt to varied environments in real time.

FACTOID

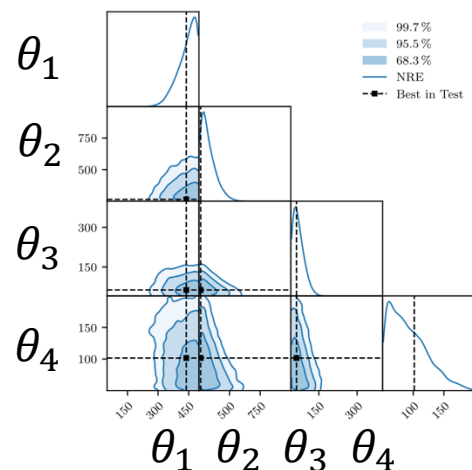

Intelligent Agent

EELS' risk-aware autonomy software is designed so the robot can pick the best path through uncertain terrain and make decisions to keep itself safe.

Design Exploration Using Likelihood Ratio Estimates

We sample from the available design choices

$$\theta \sim p(\theta | x_{\text{objective}})$$

Distribution over θ

This results in multiple valuable designs (MVDs)

Cobb et. al. "Direct Amortized Likelihood Ratio Estimation." In Proceedings of the AAAI Conference on Artificial Intelligence, vol. 38, no. 18, pp. 20362-20369. 2024.

Trustworthy Foundation Models and Bayesian LORA

LLM Bayesian Post-Processing: [Semantic Clustering](#)

LLM Bayesian Finetuning: [Bayesian LORA](#) (accepted at [UAI 2025](#))

[Enhancing Semantic Clustering for Uncertainty Quantification & Conformal Prediction by LLMs.](#) Kaur et. al. [Workshop on Statistical Frontiers in LLMs and Foundation Models @ NeurIPS 2024](#)

A combination of finetuning with uncertainty quantification LORA adaptors and post-hoc consistency analysis can help detect when foundation models are confabulating/hallucinating.

Semantic Verification of Smaller Models Using Foundation Models

Leverage other large ML models like CLIP and LLMs to “understand” concept representations and verify semantic properties such as “car is likely metallic”, “something with a tail is unlikely to be a car”

ResNet18

Number of parameters: 11.7M

CLIP (clip-vit-large-patch14)

Number of parameters: ~500M

Smaller models tend to learn **spurious correlations**: over-parameterization leads to better generalization and eventually memorization of hard-examples. Can we **use larger models to verify smaller models** and check whether the relationships learned in the smaller model are consistent with those in the larger model?

Birds(x) :- in(a1,x), wings(a1), in(a2, x), beak(a2), in(a3,x), patterned(a3)

Concept-based Analysis of Neural Networks via Vision-Language Models. Mangal et. al. SAIV 2024

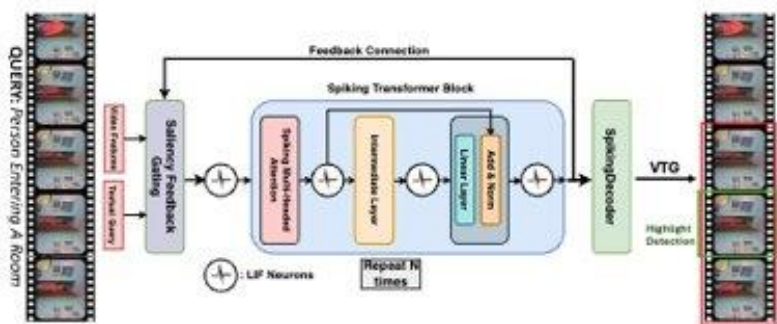

Debugging and Runtime Analysis of Neural Networks with VLMs. Hu et. al. CAIN 2025

Foundation Models can be used as specification to verify and repair smaller models.

Embodied AI with low SWAP: Spiking NNs and Backprop-free Learning

Is this good enough? Landauer's principle states that the minimum energy needed to erase one bit of information is $k_B T \ln 2$ which approximates to 3×10^{-21} J. 2020 chips (TSMC 5nm node) consume a factor of 1,175x as much energy. Yet, after improving by 15 orders of magnitude, we are close to the limit – only 3 orders of magnitude improvement are left.

Second-Order Forward-Mode Automatic Differentiation for Optimization. Cobb et. al. OPT Workshop on Optimization for Machine Learning @ NeurIPS 2024

SpikingVTG: Saliency Feedback Gating Enabled Spiking Video Temporal Grounding. Bal et. al. Machine Learning and Compression Workshop @ NeurIPS 2024

Alternative architectures such as Spiking Neural Networks and low-memory optimization methods such as forward gradients can enable low SWAP AI.

Semantic Verification of Smaller Models using VLMs

- Formal verification tools (e.g. NNV, Reluplex, Beta-crown, Sherlock) verify robustness (using L_p norm) of representations in the latent space.
- Leverage other large ML models like CLIP and LLMs to “understand” concept representations and verify semantic properties such as “car is likely metallic”, “something with a tail is unlikely to be a car”

ResNet18

Number of parameters: 11.7M

CLIP (clip-vit-large-patch14)

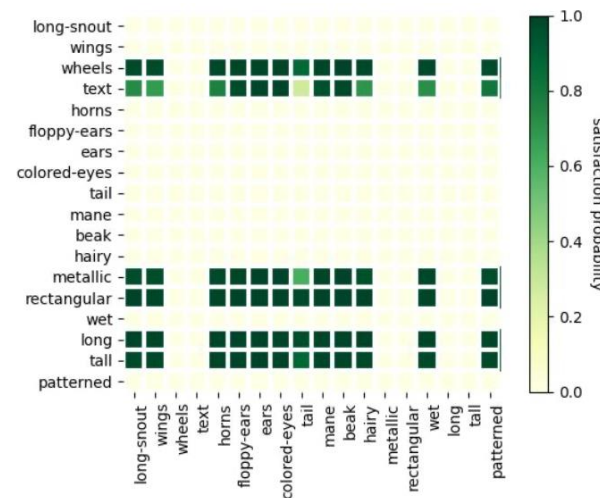

Number of parameters: ~500M

Smaller models tend to learn **spurious correlations**: over-parameterization leads to better generalization and eventually memorization of hard-examples.

Key insight: Can we **use larger models to verify smaller models** and check whether the relationships learned in the smaller model are consistent with those in the larger model?

We can do so for single examples (**runtime monitoring**) and we can also check for aggregate relationships in the model (**design-time verification**).

Semantic Verification of Smaller Models using VLMs

Runtime Monitoring Using VLMs

GPT-4o

LLaVA 1.5 (L1.5)

LLaVA 1.6 Mistral (L1.6 Mis)

LLaVA 1.6 Vicuna (L1.6 Vic)

SpaceLLaVA

PaliGemma

Cambrian Phi 3 (C-Phi3)

Cambrian Llama 3 (C-Llama3)

RoadScene2Vec (RS2V)

We investigate the use Vision-Language Models (VLMs) for **extracting spatial relationships** from real images by extracting triplets of the form of (subject, relation, object) from real image datasets such as nuScenes, Waymo, and KITTI.

We used this dataset to **evaluate the spatial reasoning capabilities** of **8 state-of-the-art VLMs** using **4 different prompting strategies** for querying the VLMs

Dataset for evaluating Runtime Monitoring using VLMs

Waymo

```
[('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'rightOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego')]
```

NuScenes

```
[('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego'),  
 ('vehicle', 'b/w40-60m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego')]
```

KITTI

```
[('person', 'w25m', 'ego'),  
 ('person', 'rightOf', 'ego'),  
 ...  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego')]
```

- Datasets such as nuScenes, Waymo, and KITTI consist of driving scenes along with 3D bounding box annotations for objects and other kinds of meta-data, these datasets do not come with ground-truth annotations of spatial relationships between entities.
- We develop a generic framework that can extract ground-truth triplets from scenes using the existing annotations in these datasets.
- We created a **new dataset of road-scenes** annotated with corresponding relationship triplets.

Dataset for evaluating Runtime Monitoring using VLMs

Waymo

```
[('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'rightOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego')]
```

If there is a car within 25m of ego, AND ego speed is > 25 mph, THEN ego acceleration should be negative (braking) in the next time step.

This can be expressed in LTL

- The antecedent describes a scenario in terms of spatial relationships between the ego vehicle and other entities in a scene, while the consequent describes the desired ADS behavior.
- We capture such spatial relationships as triplets of the form <subject, spatial relation, object> suitable for use in LTL monitors

NuScenes

```
[('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'leftOf', 'ego'),  
 ('vehicle', 'b/w25-40m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego'),  
 ('vehicle', 'b/w40-60m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego')]
```

KITTI

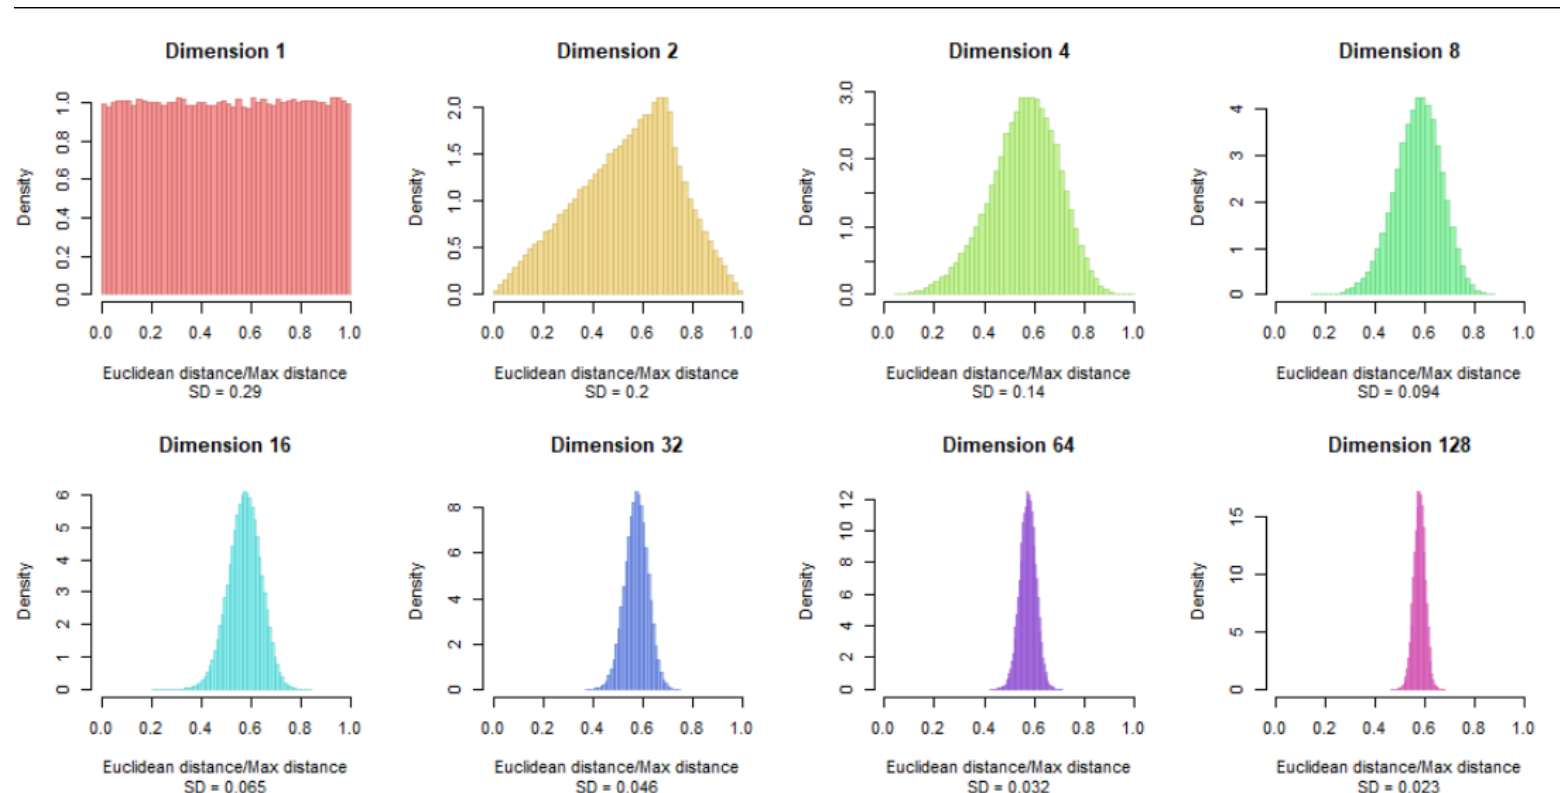

```
[('person', 'w25m', 'ego'),  
 ('person', 'rightOf', 'ego'),  
 ...  
 ('vehicle', 'w25m', 'ego'),  
 ('vehicle', 'inFrontOf', 'ego')]
```

Runtime Monitoring

SpaceLlaVA	1	11.16	0.29	0.39	0.24	0.25							

Our experiments show that while off-the-shelf VLMs have limited capability on this task, but their performance is significantly improved by **fine-tuning**.

Concentration of distances in high dimensions

Relative distance between random points sampled uniformly from d -dimensional torus

Why should we care?

- All of apparent semantics learning in machine learning relies on using projection of data to a relatively high dimensional space following by using some simple distance metrics such as cosine distance between vectors to determine “semantic similarity”
- As models grow in size and hidden layers become wider, distance concentration would inhibit prohibit semantic learning.

Generative Agents: Interactive Simulacra of Human Behavior

Figure 1: Generative agents are believable simulacra of human behavior for interactive applications. In this work, we demonstrate generative agents by populating a sandbox environment, reminiscent of The Sims, with twenty-five agents. Users can observe and intervene as agents plan their days, share news, form relationships, and coordinate group activities.

arXiv:2304.03442v2 [cs.HC] 6 Aug 2023

- **generative agents**, powered by LLMs that simulate **believable human behavior**
- Smallville with **25 agents**
- autonomously plan, interact, remember, reflect, and coordinate a Valentine's Day party showcasing emergent, lifelike social dynamics
- 2 day simulation – up to 12 agent diffusion of information

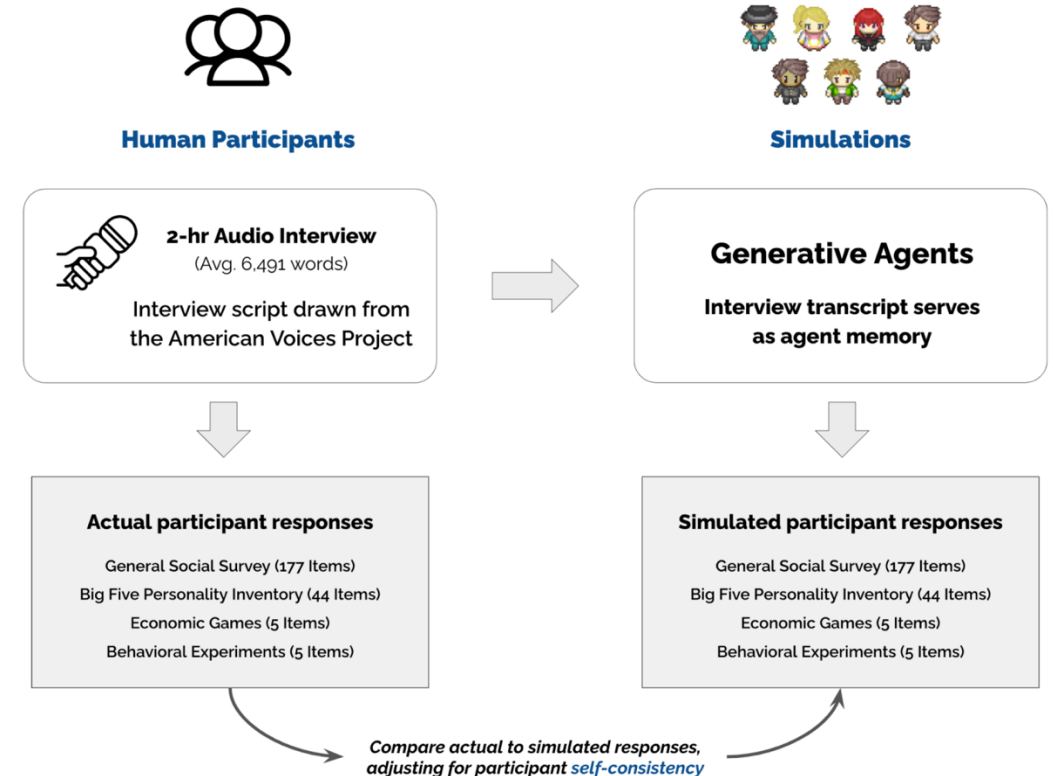

John Lin is a pharmacy shopkeeper at the Willow Market and Pharmacy who loves to help people. He is always looking for ways to make the process of getting medication easier for his customers; John Lin is living with his wife, Mei Lin, who is a college professor, and son, Eddy Lin, who is a student studying music theory; John Lin loves his family very much; John Lin has known the old couple next-door, Sam Moore and Jennifer Moore, for a few years; John Lin thinks Sam Moore is a kind and nice man; John Lin knows his neighbor, Yuriko Yamamoto, well; John Lin knows of his neighbors, Tamara Taylor and Carmen Ortiz, but has not met them before; John Lin and Tom Moreno are colleagues at The Willows Market and Pharmacy; John Lin and Tom Moreno are friends and like to discuss local politics together; John Lin knows the Moreno family somewhat well – the husband Tom Moreno and the wife Jane Moreno.

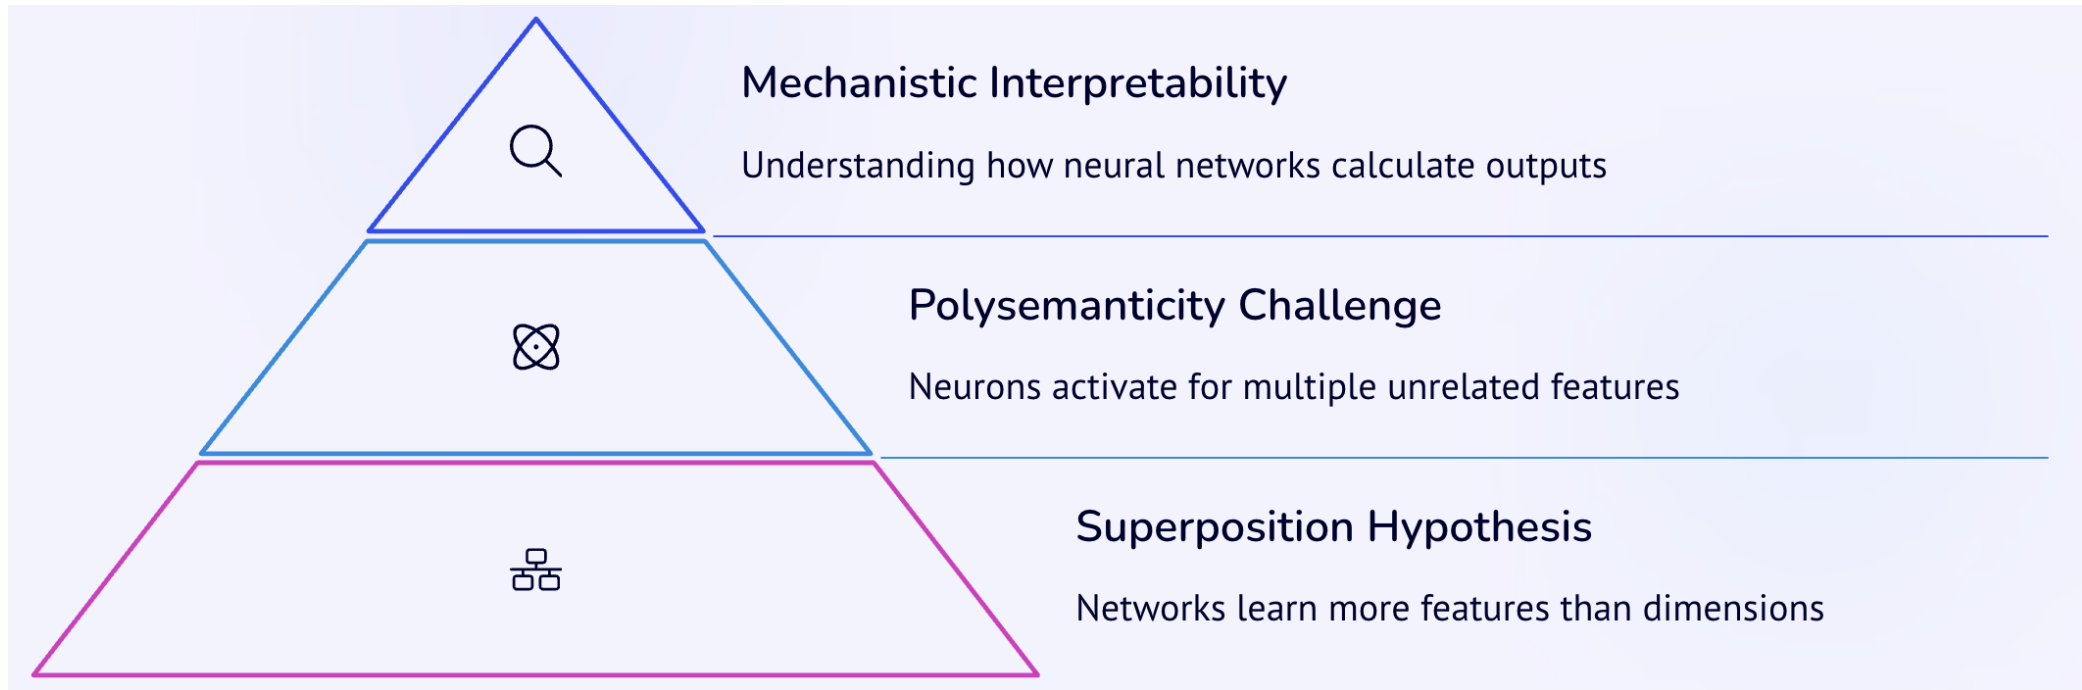

Generative Agent Simulations of 1,000 People

Authors: Joon Sung Park^{1*}, Carolyn Q. Zou^{1,2}, Aaron Shaw², Benjamin Mako Hill³, Carrie Cai⁴, Meredith Ringel Morris⁵, Robb Willer⁶, Percy Liang¹, Michael S. Bernstein¹

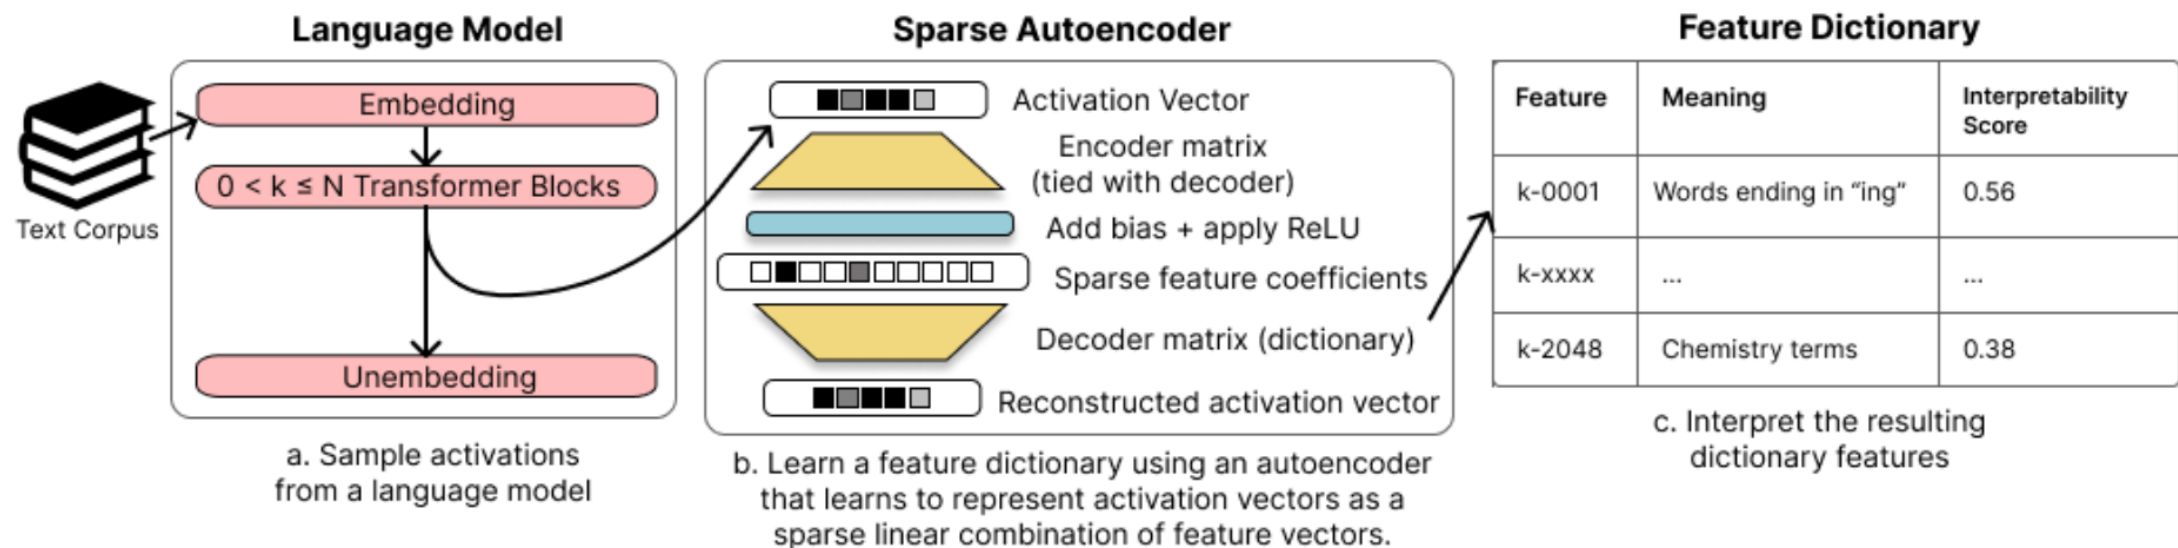

We present a novel agent architecture that simulates the attitudes and behaviors of **1,052 real individuals**—applying large language models to qualitative interviews about their lives, then measuring how well these agents replicate the attitudes and behaviors of the individuals that they represent. The generative agents replicate participants' **responses on the General Social Survey 85% as accurately as participants replicate their own answers two weeks later.**

Sparse Autoencoders

Sparse Autoencoders

Mapping polysemantic neurons from LLMs' layer to monosemantic encoded space

Sparse Autoencoders

Sample Activations

Collect internal activations from language model layers

Tinyllama1.1B model's 14 layer activations
for 'city'

Train Autoencoder

Use sparse penalty to learn dictionary of features

Train SAE with encoded space 4 times the layer

Interpret Features

Analyze resulting features with automated methods

Interpret encoded space with concepts associated
with 'city' such as 'country', 'language' etc.

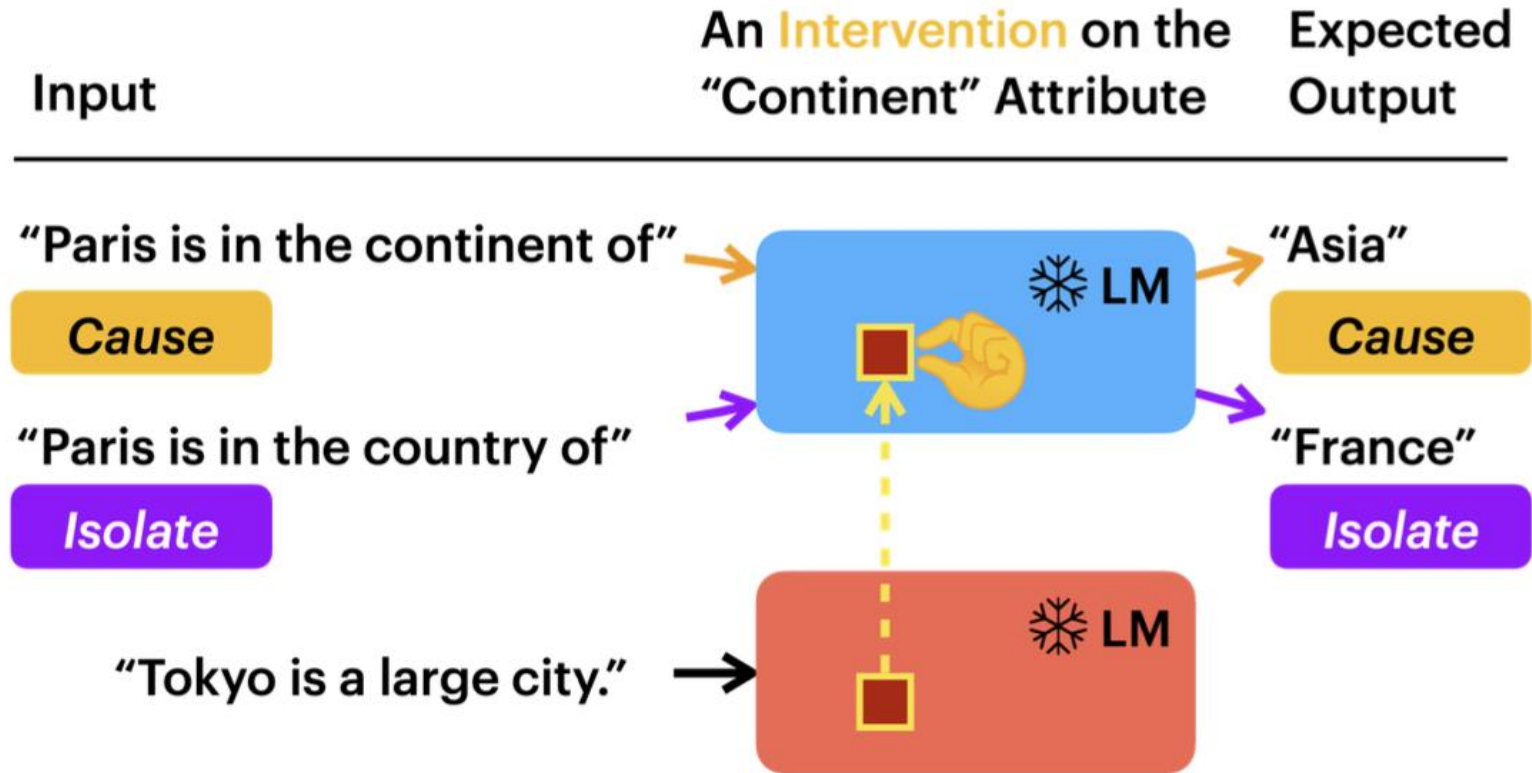

Evaluate Results

Compare interpretability to baseline approaches

Patching for 'causal' and 'isolation' scores

Evaluation via patching
